

Computational Cognitive Neuroscience

Psych 4175/5175

Professor: Randy O'Reilly

TA: Chris Chatham

1. Syllabus, student info cards, introductions.
2. What this course is all about.

The Most Interesting Thing in the Universe..

The Most Interesting Thing in the Universe..

The Most Interesting Thing in the Universe..

It is also the most complex. Computer models can help.

Physical Reductionism

Reductionism: explaining in terms of underlying mechanisms.

What mechanisms for cognition? CPU & RAM? Logic? Lisp?
Productions?

Physical Reductionism: mechanism is the *brain*.

Reconstructionism

Putting the reduced pieces back together.

Critical when there are billions of such pieces (neurons).

Computer simulations are essential.

Emergent properties:

Complexity and Levels of Analysis

The brain is very complex: billions of neurons, 5,000 x billion synapses, changing every nanosecond.

Need to abstract away from this complexity!

Is there some simpler, higher level for describing what the brain does during cognition?

In a Computer Program..

You can have three levels of abstraction (Marr):

Computational: what is overall goal?

Algorithmic: what strategy?

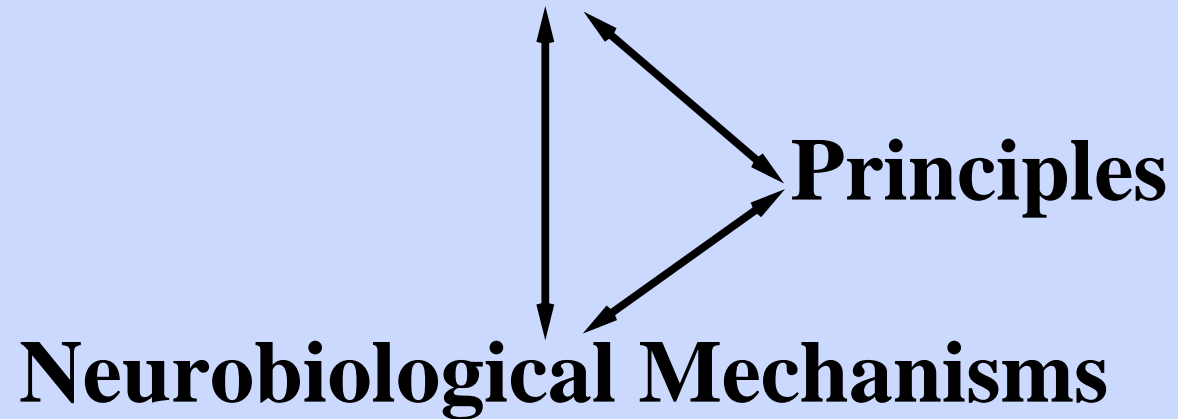

Implementational: how to physically encode?

Can we focus only on 1st two levels?

Only if you assume a particular implementation!

Our Levels

Cognitive Phenomena

Neurobiological Mechanisms and Principles

Neurons: serve as *detectors*, signal with *activity*.

Networks: link, coordinate, amplify, and select patterns of activity over neurons.

Learning: organizes networks to perform *tasks* & develop good *models* of environment.

Psychological Phenomena

Visual encoding: A network views natural scenes (mountains, trees, etc.), and develops brain-like ways of encoding them using principles of learning.

Spatial attention: Taking advantage of interactions between two different streams of visual processing, a model focuses its attention in different locations in space, and simulates normal and brain-damaged people.

Episodic memory: Replicating the structure of the *hippocampus*, a model forms new episodic memories and solves human memory tasks.

Working memory: A neural network with specialized biological mechanisms simulates our *working memory* capacities (e.g., the ability to mentally juggle a bunch of numbers while trying to multiply multidigit values).

Psychological Phenomena

Word reading: A network learns to read and pronounce nearly 3,000 English words, and *generalizes* to novel nonwords (e.g., “mave” or “nust”) just like people do. Damaging a reading model simulates various forms of dyslexia.

Semantic representation: A network “reads” every paragraph in a textbook, acquiring a surprisingly good *semantic* understanding by noting which words tend to be used together or in similar contexts.

Task directed behavior: A network simulates the “executive” part of the brain, the *prefrontal cortex*, which keeps us focused on performing the task at hand and protects us from distraction.

Advantages of Simulation Method

- Models help us understand phenomena:
 - Provides novel insights.
 - Effects of brain damage/drugs.
 - Can explain *why* things are (function).
- Models deal with complexity, span levels.
- Models are explicit:
 - Deconstruct psychological constructs.
 - Makes novel predictions.
 - Forces accountability in simulating data.
 - Completeness in all problem aspects.
- Enables complete control & understanding.
- Forces consistency & unity in framework.

Potential Traps/Problems

- Models are too simple (need multiple levels).
- Models are too complex (need a theory).
 - Which properties are relevant?
- Models can do anything:
 - Too many degrees of freedom (use same params).
 - Indeterminacy problem (many tasks).
- Models are reductionistic (reconstruct!).
- Modeling lacks cumulative research.
