**Neurons in the Dark**

- Neurons live in the dark!
- “Hear” an incredible jumble of inputs.
- Have *absolutely no idea* what is going on in the real world outside their little area of the brain..

All of this is very counterintuitive given that we tend to think of neurons as communicating in full English sentences about the weather, etc..

**Neurons only get spikes, not words!**

**The Social Network**

Neurons depend on network of “trust” built up over a long time period – only way they can overcome the jumble in the dark..

**Pandemonium Summary**

- Maybe you can see how collective action of many detectors, organized *hierarchically*, could achieve more complex cognition?
- But detection needs to be a lot more sophisticated..

**Back to the Detector Model**

How do we simulate on a computer?
Overall Strategy

- Neurons are electrical systems, can be described using basic electrical equations.
- Use these equations to simulate on a computer.
- Need a fair bit of math to get a full working model (more here than most chapters), but you only really need to understand conceptually.

The Tug-of-War

How strongly each guy pulls: \( I = g (E - V_m) \)
\( g \) = how many input channels are open
\( E \) = driving potential (pull down for inhibition, up for excitation)
\( V_m \) = the “flag” — reflects net balance between two sides

Relative Balance..

Equations..

Relative Balance..

Equations..

Equilibrium

The Full Story..
Input Conductances and Weights

- Just add ‘em up (and take the average)
  \[ g_i(t) = \frac{1}{n} \sum_{j=1}^{n} \pi_{ij} \]

- Key concept is weight: how much unit listens to given input
- Weights determine what the neuron detects
- Everything you know is encoded in your weights.

Generating Output

- If Vm gets over threshold, neuron fires a spike.
- Spike resets membrane potential back to rest.
- Has to climb back up to threshold to spike again

Rate Code Approximation

- Brain likes spikes, but rates are great!
  - Instantaneous and steady – smaller, faster models
  - But definitely lose several important things
  - Soln: do it both ways, and see what the diffs are.
- Goal: equation that makes good approx of actual spiking rate for same sets of inputs.

Sigmoidal Activation

- Threshold
- Saturating
- Smooth

Rate Code Equations

- A little bit tricky because Vm doesn’t work.
- Need to use excitatory conductance – threshold
- XX1 equation:
  \[ y = \frac{1}{1 + e^{-(E_i - \Theta)}} \]

- ge-theta:
  \[ g_e = \frac{g_e(E_i - \Theta) + g_e(E_i - \Theta)}{E_i - E_a} \]

- Tracking Vm timecourse:
  \[ \dot{V_m} = \frac{V_m - V_{rest}}{0.05(1 - V_m^2)} \]

  \[ \dot{g_e} = \left( \frac{V_m - V_{rest}}{0.05(1 - V_m^2)} \right) \dot{g_e} \]
